6.20 simplex.cpp

```cpp
/**
 * Author: Stanford
 * Source: Stanford Notebook
 * License: MIT
 * Description: Solves a general linear maximization problem: maximize $c^T
     x$ subject to $Ax \le b$, $x \ge 0$.
 * Returns -inf if there is no solution, inf if there are arbitrarily good
     solutions, or the maximum value of $c^T x$ otherwise.
 * The input vector is set to an optimal $x$ (or in the unbounded case, an
     arbitrary solution fulfilling the constraints).
 * Numerical stability is not guaranteed. For better performance, define
     variables such that $x = 0$ is viable.
 * Usage:
 *  vvd A = {{1,-1}, {-1,1}, {-1,-2}};
 *  vd b = {1,1,-4}, c = {-1,-1}, x;
 *  T val = LPSolver(A, b, c).solve(x);
 * Time: O(NM * \#pivots), where a pivot may be e.g. an edge relaxation. O
     (2^n) in the general case.
 * Status: seems to work?
 */
